

A multi-layer, multi-temporal reading of the neutrophil

Each layer measures a partial truth about the neutrophil; the error would be to force them all to say the same thing.

Four independent public datasets — different cells, species and diseases — read as complementary, **not co-measured**.
Only the metabolic layer carries a quantitative severity axis and a measured result; the other layers are schematic compositions / states.

Figure 7 · conceptual multi-layer synthesis · no sample-level fusion, no causal claim
